Q. Nos.

playload:- the Data which is transfer By the upper layer is called as playload.

* The Data packets are Stamped with the IP address of there Source & destination in their headers where. the header is heavy here

* And the Data passes through the network where the TTL - Time to live & the Compont is essential to track the Data packets across the network so it doesn't ~~Dont~~ Stuck in Endless loop.

* the checksum is being calculated to ensure the Data is Corrupted or not while transmi - Hing.

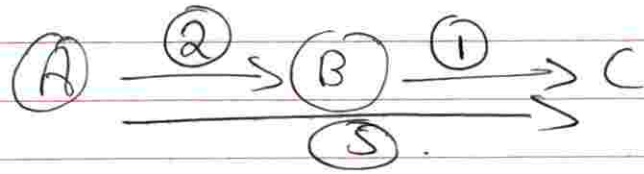

Q6
a Answer:-

Distance vector Routing (DVR):- In DVR the nodes doesn't know the network map of the whole transmission medium what it known is only the nearst neighbour to it and it calculate the distance through that neighbour. and each neighbour Share there own path to the goal node. or a ~~P~~ target node. By having this information & the nodes verify & calculate the shortest path from which the node can reach its targeted destination.

Q. Nos.

Example:-

the node A as to reach the destination node C.

* the path cost from A to C is 5 & the A approach the way from the node B where going through the node B the path cost is equal to 2+1 = 3.

DVR = min(5, 3)
= 3.

* It chooses the path through B because the A as its next neighbour as B & it is the shortest distance.

Algorithm:

Step1: Start
Step2:- Source node & destination node.
Step 3: collect the path cost to the edges & the nods which are neighbours.
Step4: calculate the nearest route
Step5: reach the route by min path cost.
Step6: Stop
Step7: close.

Q. Nos.

module-1

Q1)

ANSWER:

Data Communication: It is the process where the Data packets regardless the types like Binary Bits, making images, or audios are being transmitted across the different computers By the network.

The fundamental characteristics are:-

* Resource Sharing: where it may be the hardware or a Software the resources are being shared like Printer etc....

* portability: This helps in portability where the Data transfer aids in opening or operating the sources in the other version of computers without any issues araised.

* Protocols: the Data communication consist of the number of protocols which are responsible for the error free & collision free data transfer across the network.

Advantages of the Data Communication:-

* Used in the Hospitals: as ECG for the detection of diseases.

Module-2

Q3.

Answer:-

Stop & wait protocols:

The Stop and wait protocols are used to avoid the network jam and the collision occurs the transmission medium where the stop & wait protocols ist check whether the Data packet sent is reached safely to the destination and check the transmission medium is Busy or idel.

* according to this condition the data is being transmitted By this Protocol.

the protocols that comes under this is

PURE ALOHA:- Here the protocols waits until the line to be idel and Starts the trans-mission once the line is free.

Slotted ALOHA:-
Here the time Slotted are introduced data can't be Sent whenever it should wait for a new time Slot. & once the error is caused the whole time slot is wasted.

CSMD:- Here the transmission is made only. when the line is free. but Stile the transimission can happen from Both sides.

Q. Nos.

due to network delay & cause a problem.

CSMPS [with Ensrg].

* it fullfilly the Draw Back of CSMP where the electrical signals are Serized before pasting. the Data Stream.
